Subject: Defficient handling of objects in F2x, OR
Default CREATE, COPY and CLONE for polymorphic objects
Reference: J3-007R3

Summary

An OOP language should provide default COPY, CLONE and CREATE operators/methods for polymorphic objects. This way objects, and not just references to them, can be manipulated inside (endogenous) data-structures and other objects-that-manipulate-objects. The critical point is that these need to be accessible via the object itself, even if the type of the object is not!

CLONE is implemented via SOURCE in ALLOCATE. I propose to implement CREATE via a new MOLD argument in ALLOCATE, and COPY by modifying the meaning of intrinsic assignment for polymorphic variables to work on the actual and not on the declared types.

I illustrate the urgent need for these with a very elementary example of implementing a generic stack via arrays. Comments and suggestions on this code are very welcome. The code should really be written using types parameterized with types (a.k.a. templated types), but this is beyond repair for this revision of the language.

Motivation

In Fortran 2002 (and other OOP languages), polymorphic objects are implemented via dynamic references to them, i.e., POINTER or ALLOCATABLE polymorphic variables. Fortran 2002 provides excellent OOP facilities for manipulating these polymorphic references to objects (see my comments on lack of type specification and overuse of SELECT TYPE though). Thus implementing exogenous dynamic data-structures is supported well. But the language has profound deficiencies when dealing with the objects themselves, so that implementing endogenous structures (and these are very common in scientific programming), is all but impossible.

Eiffel is an OOP language whose design I value greatly (though I would not trade it for Fortran, of course!). It provides three default methods for any object: CREATE, COPY and CLONE

These three are fundamental operations needed to manipulate objects (and not just references to them) directly. Note that these methods are accessible through the object itself, without access to its type. In the current version of the Fortran draft, CREATE (structure constructors) and COPY (assignment inside SELECT TYPE) are only accessible if the type is accessible.

CLONE is at present the only one provided in F2002 via the SOURCE argument to ALLOCATE. I feel strongly that the other two need to be provided also. CREATE can most easily be provided by adding a MOLD argument to ALLOCATE similar to the SOURCE argument, which would only give the type of the allocated data, but not the contents. This would allow one to allocate an array of a given type given only a scalar of that type, which is needed, for example, to design custom allocators for various dynamic data structures.

COPY is trickier. I think it should be provided by modifying the meaning of intrinsic assignment for polymorphic variables to work on the actual and not on the declared types. I propose two possible interpretations in the case when the dynamic types of the left and right hand sides defer, and propose to accept the simpler of the two choices. This also requires a modification of the way base component selection works for polymorphic objects, so that the current meaning of intrinsic assignment can be used if needed (for efficiency). This will also be proposed in a separate paper.

Example: Array-based stack

A homogeneous stack can be implemented via an array. The allocation and deallocation of the array should be handled inside the stack implementation. But at present this is not possible in Fortran since the type of the allocated array is dynamic and cannot be given to ALLOCATE. Furthermore, when the stack fills up, the contents of the array should be copied to a larger array (reallocation). Again, this copy is very hard to do in Fortran 2002, since intrinsic assignment works on the declared types. One must therefore ask clients of the Endogenous_Stack class to themselves implement defined assignment and creation. This is unnecessary and very cumbersome for such a common and elementary application.

Here is how the stack would be implemented in my modified Fortran 2002. Later I will write this in what I think should be in Fortran 200+ (i.e., the next revision), using generic objects (templates in C++, unconstrained generic type parameters in Eiffel).

```

MODULE Endogenous_Stacks
  ! For homogeneous stacks only!
  ! NOTES:
  ! CREATE, COPY and CLONE are all needed and used in this example.
  ! Data is not carefully encapsulated--assume the user is trustable!
  ! Memory allocation failure is also *not* checked!

  TYPE, EXTENSIBLE, PUBLIC :: Endogenous_Stack
    CLASS(*), POINTER :: stack_mold=>NULL()
    ! What is this a stack of?
    INTEGER :: actual_size=0
    INTEGER :: expected_size=1000
  CONTAINS
    PROCEDURE, DEFERRED, PASS(stack) :: PushOnStack, PopOffStack
  END TYPE Endogenous_Stack

  ABSTRACT INTERFACE
    FUNCTION PushOnStack(stack,element) RESULT(success)
      CLASS(Endogenous_Stack), INTENT(INOUT) :: stack
      CLASS(*), INTENT(IN) :: element
      LOGICAL, INTENT(OUT) :: success
    END FUNCTION PushOnStack
    FUNCTION PopOffStack(stack,element) RESULT(success)
      CLASS(Endogenous_Stack), INTENT(INOUT) :: stack
      CLASS(*), INTENT(OUT) :: element
      LOGICAL, INTENT(OUT) :: success
    END FUNCTION PopOffStack
  END INTERFACE

END MODULE Endogenous_Stacks

MODULE Endogenous_Array_Stacks
  USE Endogenous_Stacks

  TYPE, EXTENDS(Endogenous_Stack), PUBLIC :: Endogenous_Array_Stack
    CLASS(*), DIMENSION(:), ALLOCATABLE :: storage
    ! Array-based implementation
  CONTAINS
    PROCEDURE, PASS(stack) :: PushOnStack=>PushOnArrayStack, &
      PopOffStack=>PopOffArrayStack
  END TYPE Endogenous_Array_Stack

CONTAINS

  FUNCTION PushOnArrayStack(stack,element) RESULT(success)
    CLASS(Endogenous_Stack), INTENT(INOUT) :: stack
    CLASS(*), INTENT(IN) :: element

```

```
LOGICAL, INTENT(OUT) :: success

CLASS(*), DIMENSION(:), ALLOCATABLE :: temp_storage
! For reallocation

IF(.NOT.ASSOCIATED(stack_mold)) THEN
  WRITE(*,*) "No mold for stack!"
  success=.FALSE.
  RETURN
ELSE
  IF(.NOT.SAME_TYPE_AS(stack_mold,element)) THEN
    WRITE(*,*) "Wrong argument type for stack push"
    success=.FALSE.
    RETURN
  END IF
END IF

! No allocation error handling here for now:
IF(.NOT.ALLOCATED(stack%storage)) &
  ALLOCATE(stack%storage(stack%expected_size), MOLD=stack_mold)
! Use the MOLD argument to CREATE the array

stack%actual_size=stack%actual_size+1
IF(SIZE(stack%storage)<stack%actual_size) THEN

  ! Reallocate the stack storage
  ALLOCATE(temp_storage(SIZE(stack%storage)), MOLD=stack_mold)
  temp_storage=stack%storage
  ! Use extended assignment to COPY the stack contents

  DEALLOCATE(stack%storage)
  ALLOCATE(stack%storage(2*SIZE(temp_storage)+1), &
    MOLD=stack_mold)
  ! Double the stack size
  stack%storage(1:SIZE(temp_storage))=temp_storage
  ! Copy the contents back

  DEALLOCATE(temp_storage)
END IF

stack%storage(stack%actual_size)=element
! The actual push, also a COPY

success=.TRUE.
RETURN
END FUNCTION PushOnArrayStack

FUNCTION PopOffArrayStack(stack,element) RESULT(success)
CLASS(Endogenous_Stack), INTENT(INOUT) :: stack
CLASS(*), INTENT(OUT) :: element
LOGICAL, INTENT(OUT) :: success

IF(stack%actual_size<1) THEN
  ! Empty stack
  success=.FALSE.
  RETURN
END IF

ALLOCATE(element, SOURCE=stack%storage(stack%actual_size))
! Now use CLONE via SOURCE
stack%actual_size=stack%actual_size-1

success=.TRUE.
RETURN
END FUNCTION PopOffArrayStack
```

END MODULE Endogenous_Array_Stacks

Solution

To fix the above deficiency, I propose to add a MOLD argument to ALLOCATE, with the same semantics as SOURCE, but without the contents in the lines 110:8-10. The mold variable will then simply serve as a type template for the creation (allocation) of the new object, and can be a scalar even if the allocate-object is an array.

Intrinsic assignment should also be modified to work with the dynamic, and not the declared type of polymorphic variables. This is a trickier issue which should be discussed separately from the general need of a COPY operation, no matter how this operation is actually provided.

Problems and Alternatives

CREATE

Fortran does not really have creation operators a-la C++. However, we do have default constructors, which are the ones most commonly used and needed. If something more is needed, the user should make a type-bound generic constructor. The default constructor should however be accessible via the object itself, without the need to access its actual type.

To implement allocation with SOURCE, the compiler only needs to know the size of the allocation. There is no need to initialize the allocated storage to anything since the contents of the source is immediately copied into the new storage. However, for MOLD, it is not trivial to initialize the storage. In particular, if we want default initialization to happen, then compilers really need to create an actual creation operator (a default one) for all extensible types (that is, a pointer to a creation procedure must become a part of the class slot table). I do not see this as any problem, since there is only one slot table per type and there is no overhead other than a minimal extra work on the part of the compiler.

However, it is also possible to specify that only default initialization of the base type will happen when allocating from a MOLD. I find this undesirable, but acceptable.

COPY

Efficiency

A major issue with extending intrinsic assignment to be a COPY method is efficiency and implementation. Will the need for type checking slow down programs that do not need this COPY? To prevent this, and also to allow a greater expressivity in the language, one needs to allow the selection

```
polymorphic_object%base_type
for objects declared with
CLASS(base_type), ... :: polymorphic_object
so that the present form of intrinsic assignment, i.e., working with the declared (base) type, can still be done:
```

```
CLASS(base_type), POINTER :: object_1, object_2
...
object_1%base_type=object_2%base_type ! Copies only the base
```

Exact meaning of polymorphic assignment

Another issue, which is to be decided by a majority, is what to do when the dynamic types of object_1 and object_2 do not match. I see two possibilities:

1. Copy the part in common, i.e. choose the type in the type hierarchy where the two types diverge and copy it:

```
object_1=object_2
```

is really

```
object_1%last_common_type=object_2%last_common_type
```

Since object_1 and object_2 must at least share the base type, there will always be some useful action performed by this copy.

2. (Preferred) If the rhs type is a descendent of the lhs type, then copy the child (smaller) portion. Otherwise just copy the base part:

```
object_1=object_2
```

is really (this is not legal Fortran other than in a SELECT TYPE when the types of object_1 and object_2 are accessible though):

```
IF(EXTENDS_TYPE_OF(A=object_1,MOLD=object_2) THEN
  object_1%type_of_object_2=object_2
ELSE
  object_1%base_type=object_2%base_type
END IF
```

3. Almost the same as choice (2):

```
IF(EXTENDS_TYPE_OF(A=object_1,MOLD=object_2) THEN
  object_1%type_of_object_2=object_2
ELSE IF(EXTENDS_TYPE_OF(A=object_2,MOLD=object_1) THEN
  object_1=object_2%type_of_object_1
ELSE
  object_1%base_type=object_2%base_type
END IF
```

The third option is a minor variation of the second one. I do not have a clear preference for either one, though I expect the second option will be more efficient and simpler to implement. In all applications I can think of, choice 2 will do. It also has the advantage of being clear and void of ambiguity, and it can also be implemented as a type-bound procedure for any polymorphic type, just like creation. But as already stressed in this paper, the need is to provide it as a default operator for all polymorphic objects.

Edits

Will be written after comments are received.
